

Potential Informed Trading on Polymarket

View. I would submit three potential insider-trading candidates from the reviewed market set. `Kevindoto` is the best market-structure lead because the wallet expressed a paired view inside the same Spotify ranking complex: The Weeknd would finish third and Drake would not. `AllYourMoniesAreBelongToMe` is the best size-anomaly lead because the BTS album-sales position was roughly 116 times the wallet's prior median trade size. `cookiejar` is the cleanest production-access lead because it bought a Beast Games result market 38 to 48 days before resolution, when the show result was likely already known inside the production chain.

The core idea is not "large wallet won a trade." It is that these wallets entered correct-side positions in markets where a specific group could plausibly know the answer earlier than the public: streaming platforms, labels, distributors, chart vendors, or production teams.

Screen and Heuristics

I reviewed **154 resolved markets across 42 events**, covering **\$211.9 million** of market lifetime volume and **205,362 pulled trades from 44,607 wallets**. The pipeline uses two screens (see `heuristics.md`): a stricter **ranking screen** (20 to 70 cents, \$5,000, 48 hours) that scores the whole wallet universe, and a wider **triage screen** that surfaces candidates for manual review. The candidate detail below comes from the triage screen, which keeps clusters where the wallet bought the ultimately winning contract at **20 to 85 cents**, at least **24 hours before resolution**, with at least **\$3,000** of notional buying in that market.

Heuristic	Why it matters	Candidate hit
Specific information owner	Insider theories are stronger when the market maps to a real access point.	Spotify ranking data, album-sales tracking, production-result knowledge.
Non-obvious entry price	Buys at 40 to 80 cents still have downside; this excludes near-certain 99-cent cleanup.	All four selected wallet-market rows entered below 80 cents on average except cookiejar at 78.2 cents.
Clustered or paired conviction	Repeated buying, or a linked long/short view in the same event, is stronger than one lucky fill.	Kevindoto bought both The Weeknd YES and Drake NO in the same Spotify rank complex.
Wallet-relative abnormality	A smaller dollar trade can still be important when it is large for that wallet.	AllYourMonies' BTS position was about 116 times prior median trade size.
Contract movement after entry	A real lead should survive later price volatility and resolve in the predicted direction.	Each selected contract later traded to 99.9 cents before resolving at 1.00.

Candidate Detail

Priority	Wallet	Position	Why it looks insider-shaped
1	<code>Kevindoto</code> <code>0xcd71fd...d127</code>	Bought \$10,520 of The Weeknd YES at 45.3 cents average and \$5,549 of Drake NO at 40.9 cents average.	The paired trade is the signal: one wallet expressed both sides of the third-place Spotify ranking question. A plausible source would be platform analytics, label dashboards, distributor data, or unpublished year-end ranking snapshots.
2	<code>AllYourMoniesAreBelongToMe</code> <code>0x856484...84b2e</code>	Bought \$5,747 of BTS "Arirang" debut-week sales below 3 million at 71.6 cents average, 42 to 49 days before resolution.	Album-sales thresholds are natural information-asymmetry markets. Labels, distributors, chart-reporting vendors, and sales-operations teams can see preorder or tracking signals before the public.
3	<code>cookiejar</code> <code>0x614ef9...4f1b</code>	Bought \$5,806 of the Beast Games contestant-number 151-175 YES contract at 78.2 cents average, 38 to 48 days before resolution.	This is the cleanest role-conflict story. If the season was filmed and edited, someone in production, casting, post-production, or the contestant network could know the result long before the public market resolved.

Contract Movement and Resolution

The free Polymarket trade API shows that these were not simple endgame sweeps. The contracts still moved against the candidate wallets after entry, then confirmed into resolution.

Wallet / market	Entry average	Worst price after first buy	Worst price after last buy	Last pre-resolution trade	Resolution
Kevindoto / Weeknd third on Spotify	0.453	0.112	0.339	0.999	YES won
Kevindoto / Drake third on Spotify	0.409	0.110	0.357	0.999	NO won
AllYourMonies / BTS sales below 3m	0.716	0.497	0.750	0.999	YES won
cookiejar / Beast Games 151-175	0.782	0.500	0.667	0.999	YES won

Contract Movement After Candidate Entry

Black dots mark the candidate wallet's qualifying buys. Each contract ultimately resolved at 1.00.

Interpretation

The notional floors used here (\$5,000 for ranking, \$3,000 for triage) are not too low for this kind of work. A pure whale threshold would miss stealthier insider behavior, and Polymarket wallets can be meaningful even when the notional looks modest in institutional terms. For this assignment, the better signal is a bundle: correct side, non-obvious price, specific information owner, abnormal wallet behavior, and favorable contract movement after entry.

Timing also depends on the market. A production-result trade can be suspicious weeks before resolution because the result may already be fixed internally. A streaming-rank trade may cluster closer to resolution because the informational edge comes from late internal dashboards or ranking snapshots. These three wallets fit those different timing patterns.

Artifacts: [data/candidate_wallet_leads.csv](#) , [data/candidate_market_movements.csv](#) , [data/candidate_market_price_points.csv](#) , and [report/candidate_market_movements.png](#) . The candidate list is a triage queue for tracing and attribution, not a legal conclusion. Some wallet history fields are capped by public endpoints; the contract-movement checks come from market-level trade API data.
