

Potential Informed Trading on Polymarket

Executive view. I would submit three wallets for follow-up. **Kevindoto** is the strongest market-structure case: one wallet bought both sides of the same Spotify ranking thesis, The Weeknd to finish third and Drake not to finish third. **AllYourMoniesAreBelongToMe** is the clearest size anomaly: the BTS sales bet was roughly 116 times the wallet's prior median trade. **cookiejar** is the clearest production-access case: it bought a Beast Games outcome weeks before resolution, when the result may already have been known inside the production chain.

The pattern is not just that these wallets won. It is the combination of correct-side buying, non-obvious prices, and markets where a specific group could plausibly know the answer earlier than the public.

Screen and Heuristics

The review covered **154 resolved markets**, **\$211.9 million** of market lifetime volume, and **205,362 pulled trades**. I used a strict screen for the full wallet universe, then a wider triage screen to find candidate rows for manual review.

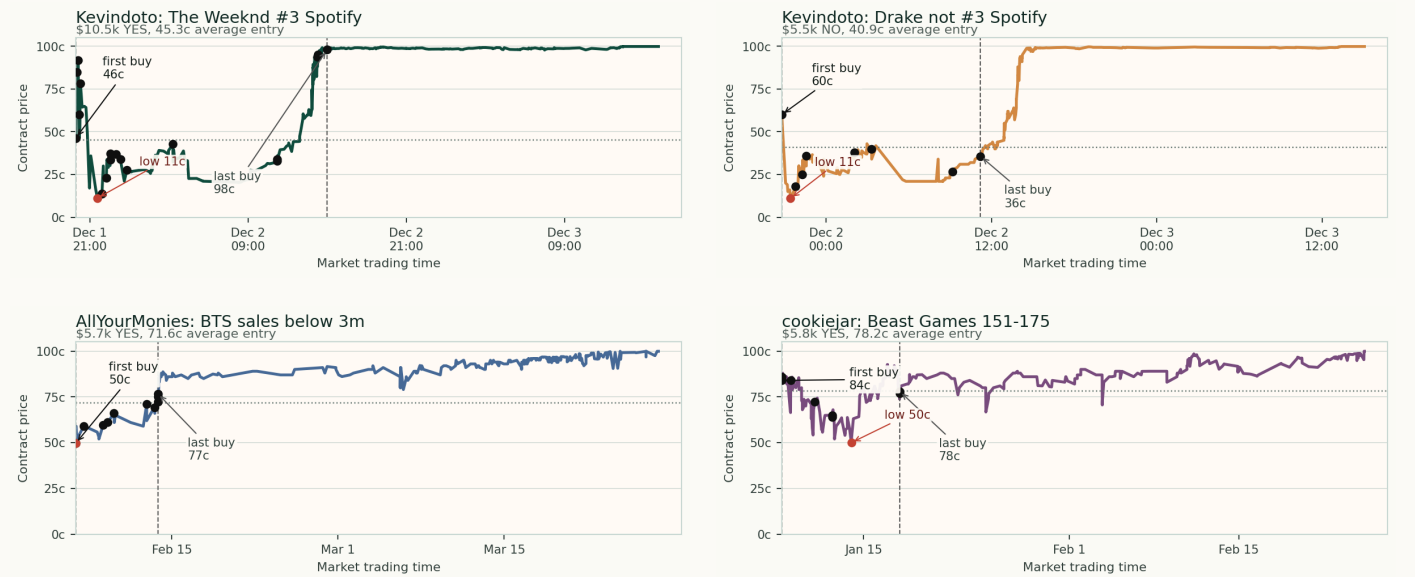

Heuristic	What it tests	How it showed up
Information access point	Market outcome depends on data a small group may see early.	Spotify ranks, album sales, production results.
Price still had downside	Entries were not 99-cent cleanup trades.	Selected positions averaged 40.9c to 78.2c.
Wallet behavior stood out	Trade pattern was unusual for the wallet or market complex.	Paired Spotify view, 116x prior median size, early production-result bet.

Candidate Detail

Wallet	Market	Position	Insider-style read
Kevindoto 0xcd71fd5370880f3d92bb941e628c05840fe0d127	Spotify third-place artist: Weeknd YES / Drake NO	\$16.1k total at 43.8c weighted average	Paired ranking view pointing to platform, label, or distributor data.
AllYourMoniesAreBelongToMe 0x8564848285e54c65f6cc2e3930b49362fbd84b2e	BTS "Arirang" debut-week sales below 3m	\$5.7k YES at 71.6c average	Sales-threshold bet far above the wallet's normal trade size.
cookiejar 0x614ef98a8be021de3a974942b2fb98794ff34f1b	Beast Games contestant 151-175 wins	\$5.8k YES at 78.2c average	Production-result market where the answer may have been known before airing.

Entry Timing and Contract Movement

The charts mark each wallet's entry window. In all four markets, the contract later moved against the wallet before finishing on the side it bought.

Market	Entry avg.	Worst after entry	Won side
Weeknd #3	45.3c	11.2c	YES
Drake not #3	40.9c	11.0c	NO
BTS sales <3m	71.6c	49.7c	YES
Beast Games 151-175	78.2c	50.0c	YES

Interpretation

The **\$3,000 to \$5,000** notional range is not too low for this assignment. A pure whale filter would miss quieter insider-style behavior. The more useful signal is the bundle: knowable-by-few market, non-obvious price, unusual wallet behavior, and price action that later confirms the position.

Timing depends on the market. A production-result trade can be suspicious weeks before resolution. A streaming-rank trade can cluster closer to resolution if the edge comes from late platform or label data.

Submission Methodology Appendix

This appendix maps the memo to the four requested tasks so the document can stand on its own without sharing the full GitHub repository.

Assignment task	What I did	Result
Data collection	Public Polymarket markets, trades, wallet stats, and refreshed trade API data for selected contracts.	154 markets, 205,362 trades, 44,607 wallets.
Heuristic design	Explainable screen: access point, non-obvious price, wallet behavior, wash/noise filter, contract movement.	No black-box score in the memo.
Application to traders	Screened wallet-market clusters, then manually reviewed the strongest rows.	Three wallets, four positions.
Ranking and methodology	Priority is qualitative and auditable: paired Spotify view, size anomaly, production-access logic.	Support files available on request.

If supporting files are requested, send the small artifact package rather than the full working repository.
